The application aims to provide compiler front-end level tools for performing operations on Fortran 2003 programs, such as source-to-source transformations and code analysis. The current version supports the grammar and customizations described in the Fortran 2003 standard. Future releases will expand the grammar and will likely add additional parser actions to OFP. This may be on an as-needed basis. The OFP application is currently in alpha testing, but we have tested it for a number of common source code cases and had no major issues. For a more detailed description of the application and its features, please see the following presentation: In order to get the latest development version, please download this file: It contains a README.txt file explaining the features of OFP. The source code and updated documentation are also available from Sourceforge. The application is licensed under the GPLv2 license. 27-11-2007 Open Fortran Parser Open Fort

OFP is based on ANTLR 4 and offers a consistent and easy to use parsing front-end for Fortran, with great support for Fortran 2003. While ANTLR is widely known and implemented in other languages, no similar parser has ever been implemented for Fortran. As of version 2.0, OFP is only an experimental front-end and its performance is not optimized. All the target languages supported are done so with reference to the standard, which is a helpful guide for finding errors. If something is not specified in the standard, it is implementation defined, and that's where most errors come from. As the Fortran 2003 specification is still under development and has yet to be ratified, it is possible that things have been

changed and there are still some things in the standard that will not yet be implemented in a parser. The code examples provided in this page are to be considered as compilable and executable code. The implementation of OFP is done with reference to the official specification of the ISO Fortran 2003 standard. The parser currently uses the Flex/Bison framework to parse the standard and provide lexers and parser in Java. The Java parser (not ofp) is not fully tested or fully implemented. The front-end in the "JavaParser" project is similar in many ways to the parser in the Open Fortran Parser. Since both parsers are based on the same parser, you can easily take advantage of the methods and features of one project in the other. However, the end goal of the two projects are different, as JavaParser is being developed for language servers and front-ends, as well as static code analysis tools. Main Features:

- The parser is based on ANTLR 4.0.2 and uses the lexer/parser/AST that was previously available on ANTLR's website for other languages. This is to reduce the amount of code that must be rewritten to support Fortran 2003 and yet still provide the same functionality.
- Multiple lexers are available to support the various dialects used in the Fortran 2003 standard.
- Parsers that use the Fortran 2003 standard are able to determine what the label of a routine is as it is being parsed and store this information.
- Parsers can also determine the file that a label belongs to during parsing. This is especially useful when determining labels that belong to other units, as those labels can be defined in external files.
- Parsers have the ability to determine how

## Open Fortran Parser

OFP is designed to be a Fortran 2003 compiler front-end. It can process Fortran 2003 programs with the following features.

Bytecode generation: Bytecode conversion for the following language features of Fortran 2003: Alignment and conversion of reserved words Regions of a program that have a label or statement definition Regions of a program that have a subprogram Program modules Variables Procedures

Bytecode analysis: Program analysis such as ranges of variables and ranges of expressions Block analysis such as if-then-else or do-while statements Nested block analysis such as do-while statement nested in while loop

Bytecode generation and analysis: Classifications of variables, subprograms, regions, and procedures Generation of local variable tables Generation of assignment and procedure tables

Bytecode conversion: Conversion of non-contextually recognized programs to a form that is contextually recognized Conversion of programs in different contexts or compilation units

Distribution: Encapsulation of the parser and analysis components Embedding of parser and analysis components in a JAR file Implementation of a command-line interface Implementation of an online help browser

Bytecode generation and analysis components: Support for two classifications of programs: Programs that are contextually recognized and Programs that are not contextually recognized Support for several model architectures of the bytecode generation and analysis components

Bytecode conversion: Transformation of programs in a given context to the bytecode form in another context

JAR files: JAR files contain everything that is needed to support online execution of bytecode programs

Parser: The parser is designed to be an ANTLR grammar The parser supports two approaches of controlling syntax generation. One approach is based on the lexer and parser The other approach is based on a parser specification and an interactive tool.

Installation: OFP is compatible with Java 5 or later OFP is distributed in a self-contained JAR file. A distribution manager (DM) is used to run OFP on a Unix-like operating system.

Compatibility with existing Fortran implementations: OFP provides compatibility with existing Fortran implementations, except for Cray, since its parser does not support use of the grammar keywords. However, its bytecode generation component does support the keywords and thus a converted bytecode program can be compiled by other compilers. OFP does not

## **What's New in the?**

General tools This directory contains the source code for the OFP project. All of the source code is located under the `src` directory. If you are a developer working on this project, you can run the project in several ways: - Simply start a `sublime\_text` instance and open `src/ofp.lisp`. In this case you should have an OFP project with a complete parser and interpreter. - If you don't want to run the project with `sublime\_text`, you can download the `.zip` of the project from the following link: - If you want to modify the project, you can download the project and edit the code. The project is well documented and has a commonlisp syntax highlighting function. All the code can be found in the directory `src/` of the project. This is a good place to start if you want to modify the code.
