End-stage liver disease may be the world's most successful blinding disease [1]. In recent decades, the prevalence of cirrhosis worldwide has increased almost ten-fold. This global increase is largely the result of a rapidly increasing prevalence of hepatitis C infection in non-European populations. Liver transplantation is the only potentially curative option for patients with end-stage liver disease. Despite a considerable increase in the number of patients transplanted in the past two decades, the morbidity and mortality associated with liver transplantation remains very high [2]. Contributing factors to these poor outcomes are infection (bacterial, viral, and fungal), allograft rejection, and surgical complications. Intensive antibiotic prophylaxis is one strategy that has been implemented to prevent or treat infection after transplantation. Infection after organ transplantation is an important complication that can lead to the loss of grafts, septicemia, or the development of a systemic inflammatory response [3]. The risks of transplant-related infections are strongly related to the type of transplantation procedure performed [4]. Non-intestinal solid organ transplantations are associated with an increased risk of bacterial and fungal infections [5]. The risk of infection is highest during the early postoperative period, after which the risk of infection gradually decreases [6]. Common bacterial pathogens are *Staphylococcus aureus*, *Escherichia coli*, *Klebsiella pneumoniae*, *Enterococcus faecium*, and *Pseudomonas aeruginosa*. As patient survival has increased and the number of transplanted organs has increased, infections have become increasingly important and remain the leading cause of death after organ transplantation [7]. The incidence of bacterial infection after liver transplantation has been reported as high as 65–80% [8]. Previous studies have evaluated the efficacy of prophylactic antimicrobial therapy for preventing infections after liver transplantation [9, 10]. Importantly, the use of prophylactic antimicrobial therapy for preventing bacterial infections after liver transplantation has been controversial. Several studies have demonstrated that the rates of infection after liver transplantation are similar for patients treated with and those not treated with prophylactic antimicrobial therapy [11].

Q: Regex: css white space I use jquery to get text from span elements on my page: `$('#clicker').click(function() { $('#button').text($('#span[id^=textButton]').map(function(){return $(this).text(); }).get()); $('#span[id^=textButton]').each(function(){ $(this).remove(); }); });` That's the code part that gets the text from span elements. Problem is that white spaces on the beginning or end of the line break the word (I need to keep them). Is there a way to get rid of this? A: Use "white-space: nowrap;" instead of "white-space: normal;" `$('#button').text($('#span[id^=textButton]:not([white-space: nowrap])).map(function(){return $(this).text(); }).get());` Works in FF and Chrome Fasacit, a new drug for the treatment of neutropenia. Fasacit, a derivative of amphotericin B, has been in clinical testing for over 20 years. A recent report has suggested that fasacit can be effective in adult neutropenic patients, although no data are available regarding children. We performed a trial of fasacit in 66 pediatric patients with neutropenia. Seventeen children had received fasacit for granulocytopenia from congenital infection; 21 patients had received fasacit for neutropenia from acute or chronic disease. Fifty-nine children were identified as having received fasacit for acute myeloid leukemia. Fasacit was added to chemotherapy with the goal of reducing the duration of neutropenia. The majority of patients who received fasacit for neutropenia had no significant toxicity (except for mild, self-limited, gastrointestinal symptoms). The average time of neutropenia was shortened by 47% (range -20-110%). The administration of fasacit may be useful for both the prevention of neutrop
